

#Linux apache web server status monitoring Script

##Description

This is a script monitors apache web server status.

##how it works

*The script has used stat variable to store output of systemctl and awk cmd which extracts exact status of web server.

*The script has used count_restarts and count_fail variable to store integer value.

*The script has used if condition to wheather service is running.

*The script has used nested if-else to ensure wheather service is inactive if inactive it will get restart and count_restart increased by 1.

*The script has used if condition to ensure the service has restarted or not if not then print echo msg extract exact last 30 lines of log file and store in error .log file using tail cmd then increase count_fail by 1.

*Then print another echo msgs again.

*Then print print last 20 lines of error.log file

*The script has used if condition to give an alert msg to end the script if count_fail is equal to 5.

##how to run

###Method 1:-

bash scriptname.sh

###Method 2:-

chmod a+x scriptname.sh

./scriptname.sh

##Output

*Display a warning message to end the script
